BANLUNG

The Banlung Project consists of an area of 240 square km and is located within the Ratanakiri Province and immediately south of the town of Banlung. An additional area of 127 square km has been provisionally granted that is contiguous to the north within the current project area.

The Company has undertaken an extensive soil geochemical sampling programs and stream sediment sample at Banlung in March 2006 and received highly anomalous gold results, reinforcing the potential of the Banlung Gold Project.

Prior to the systematic soil sampling over the project area this year, very little modern style exploration has taken place in 2006 an AirBorne survey was conducted.

Liberty sees this as a strong indicator for the discovery of a gold deposit and intend to progress its exploration with trenching, magnetic surveys and drilling programmes as soon as possible.

The soil anomalies are supported by excellent rockchip results which grade up to 61.8g/t gold. Other chip results from the largest soil anomaly contained 30.8g/t gold, 73g/t silver and 9.12% copper. High gold and copper grades in separate rock chip samples suggest the anomaly hosts multiple vein systems.

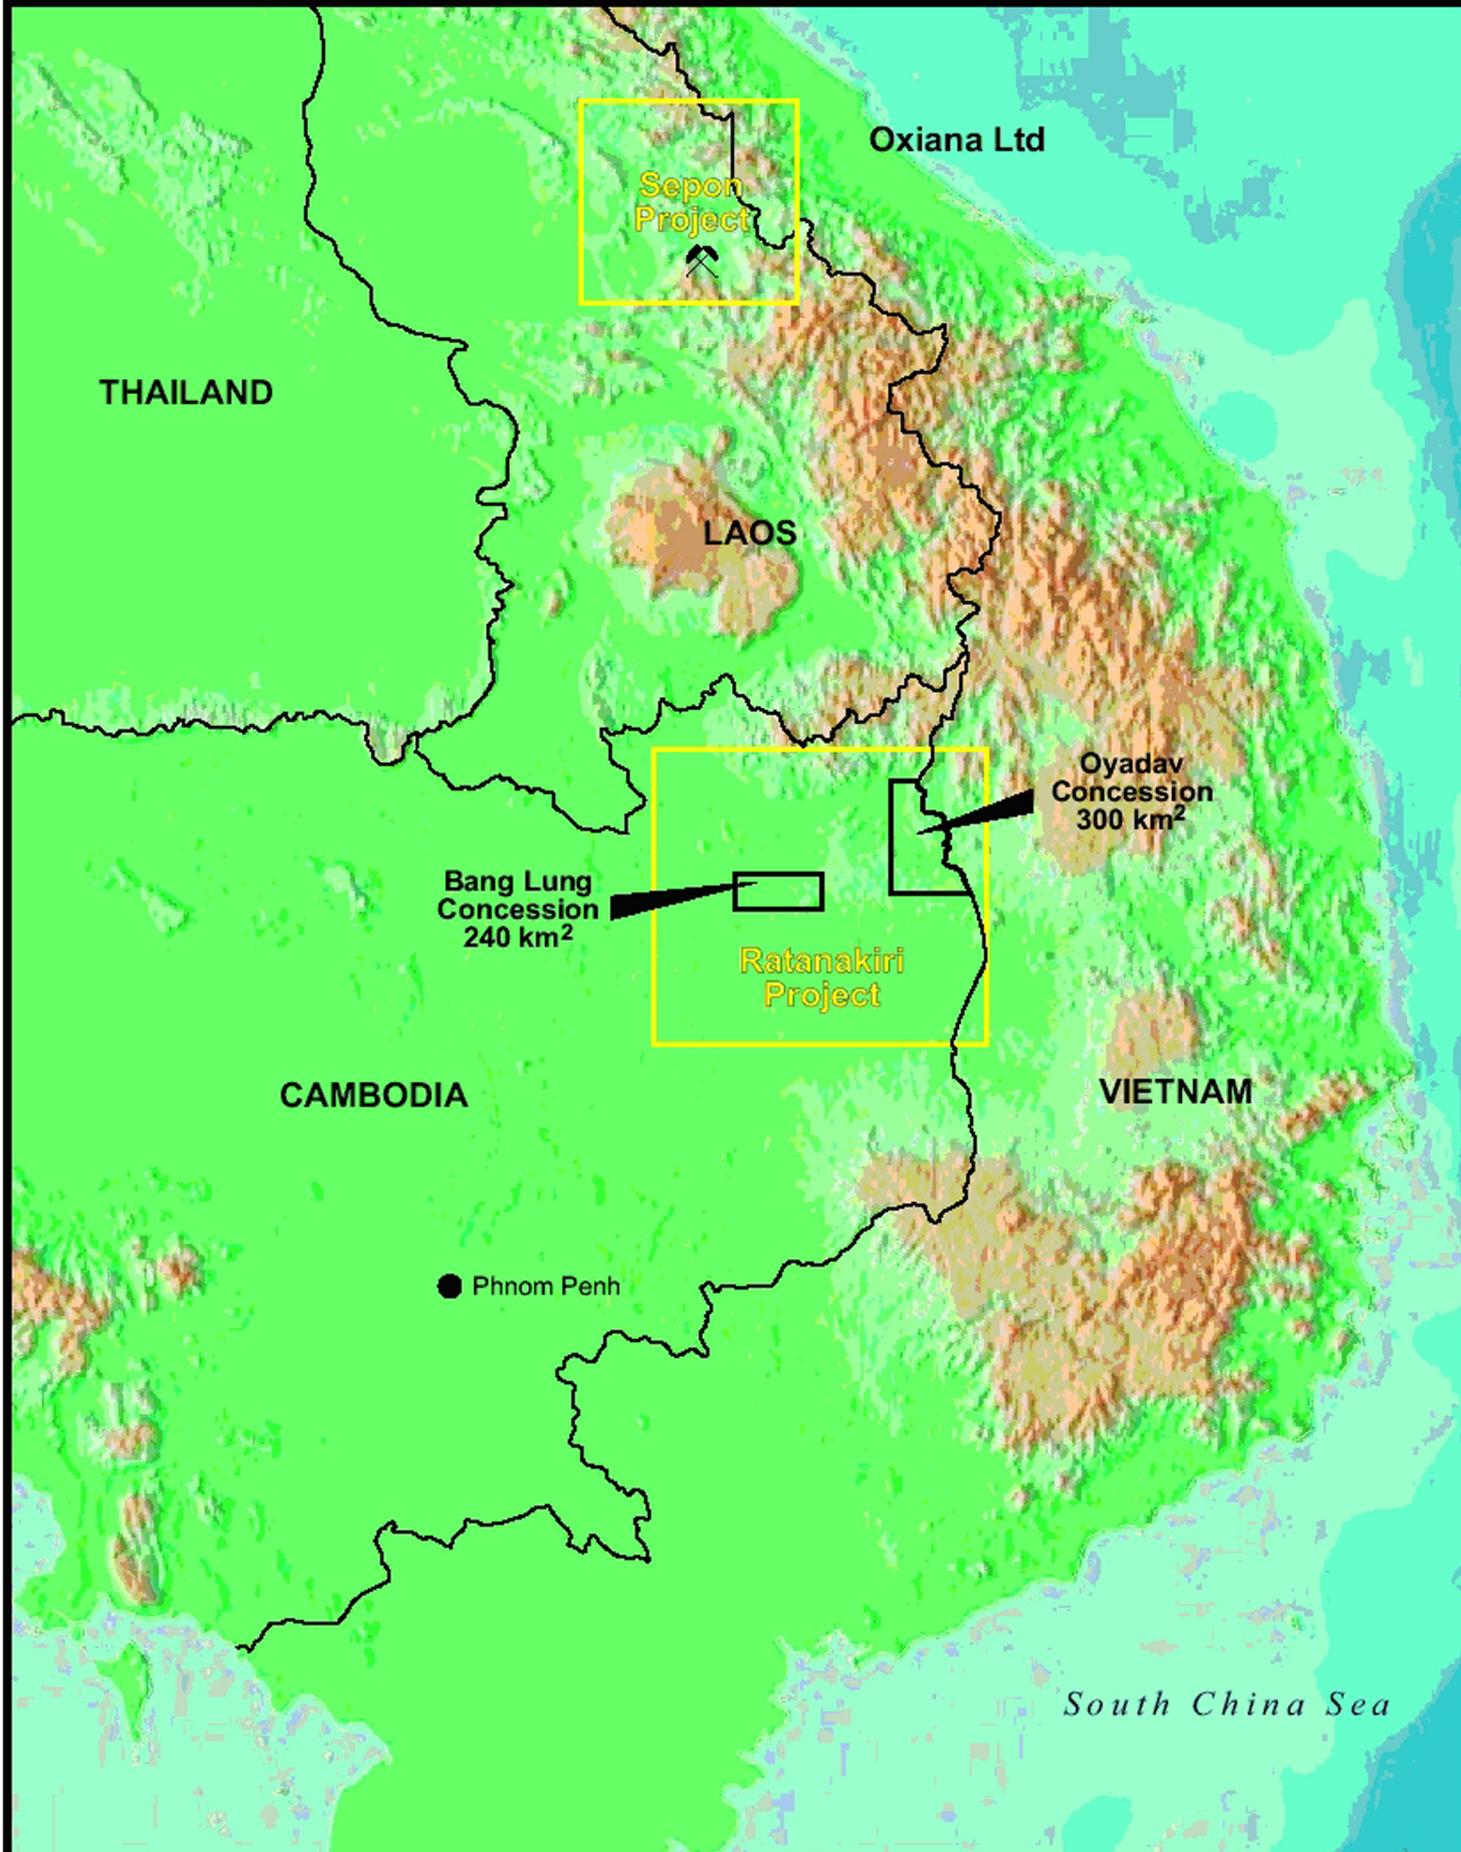

The mineralization is associated with sulphidic quartz veining on a deeply weathered geological contact. Results indicate potential for a significant deposit to exist and the Company is currently preparing to resume further exploration programmes including drilling for the 2006 year.
